## **Impacts of the Proposed Groundwater Diversions by New Mexico American Water Company in the Curry County and Portales Underground Water Basins**

### **I. Summary and Conclusions.**

On July 30, 2008 the New Mexico American Water Company (NMAW) filed with the Office of the State Engineer (OSE) an application for permit to combine a consumptive use amount of 51,139.58 acre-feet per year (afy) from its existing and proposed wells in the Curry County and Portales Underground Water Basins (Basins). The proposed purpose of this application is to enable NMAW to continue its operations for providing water to residents in the city of Clovis and other areas. The application also seeks an emergency authorization so that NMAW would continue to meet the demands of the residents of Clovis without interruption in services. Several parties protested this application including the cities of Clovis and Portales, numerous dairies and the State of New Mexico Commissioner of Public lands.

The drawdown impacts of the proposed diversions under this application were evaluated using the Curry-Portales Groundwater Flow Model (CPGFM) and the Theis Analytical (Theis) model. The CPGFM was used to compute the average drawdown in the basin due to the proposed diversions under this application. The Theis model was used to compute drawdown in nearby wells of other ownership in the vicinity of NMAW wells. Diversions under this application resulted in forty-year incremental drawdowns ranging from less than one (1) foot to more than 24 feet as computed by the CPGFM. Forty-year incremental drawdowns in nearby wells of other ownership computed by the Theis model ranged from less than one foot to approximately 19 feet in some nearby wells. These ranges of incremental drawdowns have significant adverse effects on aquifer saturated thickness and on nearby wells of other ownership. Nearby wells in the vicinity of NMAW wells may not be able to sustain production for forty years. Predictions using both models indicated that NMAW wells and nearby wells of other ownership in some areas will go dry in less than 10 years if this application is approved.

Under this application NMAW also requested an emergency authorization. The proposed wells for combining water rights are located within the same source aquifer. The time period for this emergency authorization was not specified in the application. Moreover, John Shomaker & Associates Inc. (Shomaker) indicated through personal communication that NMAW may be considering pumping groundwater under this application for only ten years. Accordingly, ten-year and forty-year drawdown impacts due to diversions under this application were evaluated using the CPGFM and the Theis model. Simulated CPGFM drawdowns ranged from less than one (1) foot to more than 10 feet. The Theis model simulated drawdowns in nearby wells ranging from less than one (1) foot to approximately 12.5 feet. Again, the drawdown effects due to diversions under this application are significant and would result in adverse effects on aquifer saturated thickness and on nearby wells of other ownership in the vicinity of NMAW wells. The predicted drawdowns exceeded the drawdown allowance applied in other basins which have a much greater water supply than the Curry County and Portales Basins.

The capability of NMAW wells to produce the applied for amount sought under this application is dubious. Measured NMAW well capacities have dropped significantly in recent years mainly due to the significant decline in water levels in the High Plains aquifer in the vicinity of these wells. Well capacities are expected to continue to decline sharply in the future and it is doubtful that these wells could sustain production for any significant length of time. Model simulations are predicting declines in water levels such that wells will become unusable. When combined with existing rights in the basin, the CPGFM simulation predicted that diversions under this application would result in most model cells in the vicinity of NMAW drying out in less than ten years. Realizing that the High Plains aquifer is the only water resource that supplies all demands in the area, prolonging the life of this aquifer should be a high priority. We recommend that NMAW revise their pumping distributions and amounts and provide us with probable future diversions from their wells that would not result in excessive drawdowns to the aquifer and to nearby wells in the area.

## **II. Introduction.**

On July 30, 2008 NMAW filed with the OSE an application to combine its existing water rights in the Curry County Basin and some water rights in the Portales Basin. The rights to be combined under this application are shown in Appendix A. Appendix A shows the file number, the quantity of water for each file number, the well location, the well capacity, and an indicator on whether an increased diversion is requested under this application from that well. The well capacity column shows the recently measured maximum quantity of water that each well can currently produce. It is apparent that most NMAW existing wells are unable to produce the required amount under the current aquifer conditions due to the rapid decline in water levels in the basin. NMAW currently claims more than 40,000 afy of groundwater rights in Curry County, and it has been experiencing difficulty in producing the current demands of about 8,000 afy as a water supply for the residents in the city of Clovis. Some NMAW wells are showing significantly reduced production due to water level declines in some areas while others are showing surpluses due to water level rises in other areas. Thus the ability of NMAW to meet the demands of its customers is constrained by either the aquifer's ability to produce the desired amounts as reflected by the wells' capacities or by the water right that limits the amount that can be produced from a particular well(s). By combining all its water rights under this application, NMAW hopes to be able to manage its water rights efficiently and withdraw more of its demands from those wells showing surpluses or a rise in water levels and less or none from those wells showing significant reduction in yield. Currently NMAW pumps less than 8,000 afy from all its wells. Appendix B shows NMAW water rights under their several permits obtained from the OSE Water Rights Division.

The area's hydrogeology consists of Quaternary alluvium (including reworked Ogallala sediments), Tertiary Ogallala formation, Cretaceous sediments, and Triassic Chinle Group mudstones and siltstones. The Triassic red beds (Chinle Group) form the base of the High Plains aquifer. The High Plains aquifer (sometimes cited as the Ogallala formation or aquifer) consists of Quaternary alluvium, Ogallala formation and Cretaceous

sediments. In this area, the lithologic logs from drilling identify the top of the Triassic red beds at depths of approximately 150 to 400 feet below ground surface (Water Rights Reporting System, WRRS, database). The High Plains aquifer is the sole aquifer for water supply in the vicinity of Clovis and Portales. The aquifer's recharge rate estimates are low (less than one inch per year) except for some sand dunes, playas or arroyos that may experience higher recharge rates (Musharrafieh & Logan, 1999). Transmissivity and storativity values are summarized in the documentation for the CPGFM (Musharrafieh & Logan, 1999).

Recognizing that under the current conditions the High Plains aquifer cannot produce the amount of water sought under this application, NMAW indicated to us through verbal communication that they would like to limit the quantity of water sought under this application to 7,103 afy or the amount that has been historically diverted. Accordingly, on September 18, 2009 NMAW provided us with a projected forty-year pumping distribution from its existing wells under this application. Under this pumping distribution, NMAW proposed to limit or cap its annual diversion from all its wells up to a maximum of 7,103 acre-feet. Subsequent discussions with Shomaker indicated that individual wells showing an increased diversion under this application may also be capped to the amount proposed in the pumping schedule. The proposed pumping distribution by NMAW is shown in Appendix C as Scenario 1.

### **III. Model Simulations.**

Drawdown effects due to the proposed diversions under this application were evaluated by performing forty-year simulations using the CPGFM and the Theis model. The superposition version of the CPGFM was used to determine the net regional drawdown effects. The incremental (or net) drawdown effects were computed as the difference between forty-year drawdowns due to projected diversions under baseline conditions and projected diversions under this application.

The Theis model simulations focused on the local assessment for the NMAW wells that showed increases in diversion under this application. In addition to these selected NMAW wells, all other nearby NMAW wells in the vicinity of each model run area were included in the Theis model even when the pumping of these additional NMAW wells remained unchanged or decreased. Using the GIS software, wells were selected based on their proximity to NMAW pumping wells of interest. Figures 1, 1A, 1B, 2, 3, 4, 5 and 6 illustrate the six areas simulated using the Theis model. The Theis model evaluates drawdown impacts for nearby wells based upon the distance from the pumping well(s). The distances are based upon available well location information from WRRS database, which may have errors, omissions or limitations as to the accuracy of the well location to the nearest quarter-quarter-quarter section. Transmissivity estimates and storativity values were calculated from the CPGFM model values by averaging the values for the area of interest.

Three scenarios were evaluated for this analysis. Scenarios 1 and 2 were evaluated using both the CPGFM and the Theis model and each included two simulations, a projected baseline simulation and a projected future simulation under this application. Scenario 3

was evaluated using the CPGFM and included only one simulation, a future simulation under this application. Scenarios 1 and 2 simulated pumping of only NMAW wells under this application. Scenario 3 simulated the full exercise of existing rights in the basin and NMAW diversions under this application.

The following paragraphs describe each simulation performed in detail.

A. Scenario 1.

- a. Baseline simulation: Baseline simulation assumed the September 18, 2009 pumping distributions among NMAW wells provided to us by Shomaker and is shown in Table 1 (Theis model) and Appendix C (CPGFM). NMAW proposed that it would limit its annual future diversions under the existing permit(s) to the historically produced amount of 7,103 afy (4,404 gpm) under baseline conditions although it could produce (if the aquifer productivity is not limiting) up to its full permitted amount under baseline conditions. The proposed total diversion cap of 7,103 afy is about 47 percent of the total measured pumping capacity (9,307 gpm) of the NMAW wells under this application.
- b. Future Pumping Simulation under this Application: Shomaker also provided us on September 18, 2009 with a probable future pumping distribution from NMAW wells under this application. Similar to baseline conditions, the proposed future diversions would be capped at 7,103 afy which may be produced from any well or group of wells if the High Plains aquifer can supply it. Also, it was proposed that individual wells showing an increased diversion under this application may also be capped to the amount proposed in the pumping schedule.

B. Scenario 2

- a. Baseline Simulation: NM OSE Hydrology Bureau developed a baseline pumping scenario based on the minimum of the well's water right and the well's measured pumping capacity provided by NMAW. This scenario represents a worst case pumping distribution for NMAW wells. As a practical operational constraint wells were pumped to 60% of their measured capacity<sup>1</sup>. The NMAW wells evaluated were limited to those under this application (Appendix A). For the baseline scenario, the water rights were divided equally amongst wells for a given file number. In a couple of instances, water rights for multiple files have been moved into a single file or combined. Some NMAW water rights in Appendix A have the type of use listed as irrigation. Since the type of use will actually be municipal, the technical evaluation considered a lower quantity of water rights would be available due to the change in use. Irrigation rights were assumed pumped at the consumptive use rate of 1.29 acre-feet per acre.

---

<sup>1</sup> Practically, wells cannot produce to their full capacity 100 % of the time. Accordingly, the reported maximum capacity for NMAW wells was reduced to 60% for this simulation.

Some pumping capacities were revised and updated by NMAW correspondence several times. The revised or updated capacities provided on August 25, 2009 (Table 1 for Theis model and Appendix C for CPGFM) were used as a basis for the maximum well yields of individual wells. For the Theis model, the baseline pumping is 20,629 afy or 12,791 gallons per minute (gpm).

- b. Future Pumping Simulation under this Application: The future pumping simulation under this application was based on well capacities. Similar to the baseline simulation, future pumping rates were reduced to 60 percent of the wells' capacities based on operational considerations. In some instances, no pumping capacity was available because either the well is not yielding due to a depleted High Plains aquifer or because no measurement was done for this well. The water right was used as the maximum pumping rate for this well. NMAW has a large amount of declared, licensed and permitted water rights, such that water rights do not represent a constraint for pumping individual wells. Table 1 (Theis model) summarizes the future pumping scenario, which totals 23,186 afy or 14,377 gpm.

#### C. Scenario 3.

- a. Scenario 3 was performed to determine the forty-year drawdown effects due to full exercise of existing rights plus NMAW diversions under this application. Baseline simulation was not needed for this scenario since the objective is to predict aquifer response if NMAW and all existing rights were fully exercised. For this scenario, NMAW diversions assumed the Scenario 1 pumping distribution.

### IV. Results.

#### A. Simulated Drawdown Effects by CPGFM.

Simulated forty-year incremental drawdown effects for Scenarios 1 and 2 are shown in Figures 7 and 9 respectively. The incremental drawdown is computed as the difference between drawdowns for future simulations under this application and the respective baseline simulation. The incremental forty-year drawdowns for Scenario 1 ranged from less than one (1) foot to approximately 19 feet and from less than one foot to approximately 24 feet for Scenario 2. The largest incremental drawdown occurred in the vicinity of NMAW wells where additional diversions under this application (Figures 7 and 9) were simulated. Based on the current saturated thickness of the High Plains aquifer and the short life expectancy of the aquifer, this magnitude of drawdown is considered to have significant adverse effects on existing water rights.

The ten-year incremental drawdown for Scenario 1 ranged from less than 1 foot to approximately 10 feet in the vicinity of NMAW wells as shown in Figure 8. Again, this

magnitude of drawdown is considered to have significant adverse effects on existing water rights.

Figure 10 shows the remaining forty-year saturated thickness under Scenario 3. It is apparent that if this application is approved and pumping was performed according to the proposed distribution, almost all the High Plains aquifer in the vicinity of the NMAW wells will be depleted in less than forty years. Actually, a significant portion of the Ogallala aquifer will dry out before the year 2020 (Figure 11) affecting both NMAW wells and nearby wells of other ownerships in the area.

#### B. Drawdown Effects on Nearby wells of Other Ownership.

Table 2 presents a summary of results for the Theis model evaluation for Scenario 1. Theis model Areas 1, 2 and 3 predict incremental drawdowns that are approximately two feet or more at nearby wells for the 40-year and 10-year simulations. The 40-year estimates of drawdown ranged from 0.0 to 13.9 feet for Area 1 (Figures 1A & 1B), which includes wells CC 659 and CC 239 amongst other NMAW pumping wells. The 10-year estimates of drawdown ranged from -1.5 to 9.1 feet for Area 1. The 40-year estimates of drawdown ranged from 0.8 to 4.7 feet for Area 2 (Figure 2), which includes wells CC 549 and CC 553 amongst other NMAW pumping wells. The 10-year estimates of drawdown ranged from -0.3 to 3.4 feet for Area 2. The 40-year estimates of drawdown ranged from 1.3 to 3.5 feet for Area 3 (Figure 3), which includes wells CC 1660, CC 1660 S and CC 1660 S2 amongst other NMAW pumping wells. The 10-year estimates of drawdown ranged from 0.4 to 2.5 feet for Area 3.

Table 3 presents a summary of results for the Theis model evaluation for Scenario 2. Theis model Areas 1, 2, 3 and 5 predict incremental drawdowns that are approximately two feet or more at nearby wells for the 40-year and 10-year simulations. The 40-year estimates of drawdown ranged from 2.9 to 16.1 feet for Area 1 (Figures 1A & 1B), which includes wells CC 659 and CC 239 amongst other NMAW pumping wells. The 10-year estimates of drawdown ranged from 0.4 to 10.3 feet for Area 1. The 40-year estimates of drawdown ranged from 1.4 to 3.8 feet for Area 2 (Figure 2), which includes wells CC 549 and CC 553 amongst other NMAW pumping wells. The 10-year estimates of drawdown ranged from 0.7 to 2.8 feet for Area 2. The 40-year estimates of drawdown ranged from 1.7 to 4.9 feet for Area 3 (Figure 3), which includes wells CC 1660, CC 1660 S and CC 1660 S2 amongst other NMAW pumping wells. The 10-year estimates of drawdown ranged from 0.7 to 3.6 feet for Area 3. The 40-year estimates of drawdown ranged from 0.5 to 2.7 feet for Area 5 (Figure 5), which includes wells CC 528 and CC 536 amongst other NMAW pumping wells. The 10-year estimates of drawdown ranged from 0.1 to 1.8 feet for Area 5.

The drawdown estimates in Table 2 and Table 3 resulted from the simulated pumping of NMAW wells and do not account for other sources of drawdown such as drawdown due to existing wells and dynamic drawdown. Also the range of water columns reported in these tables is based upon a limited number of nearby wells that have total depth and water level data for wells drilled over the last ten years. These data show a range of 12 to 124 feet for the water column. Many wells have less than 70 feet for a water column. In most cases, the water column equals the saturated thickness because drilling most often

stops at the top of the Chinle formation or red beds. In some instances the water column does not represent the saturated thickness. For example, shallow wells do not fully penetrate the High Plains aquifer, or a well may extend beyond the contact between the High Plains aquifer and the Chinle formation. Wells drilled during the irrigation season show seasonal lows while wells drilled at other times of the year would tend to show a greater saturated thickness. Also, erosional features (e.g., channels) in the Chinle formation may create a variable saturated thickness for the High Plains aquifer. As presented in Tables 2 and 3, water column estimates for the last 10 years were not adjusted for the intervening years of water level declines after drilling the well. If adjusting the water columns for wells drilled from 2000 to 2008 in Theis Areas 1 and 6, the current length may be reduced by up to 40 feet in nine years. In Theis Areas 2 through 5, recently drilled wells may have water column adjustments up to 9 feet in 9 years. These water column adjustments are based on water level trends described in Section V.

Appendix D tabulates the wells used for the six areas that were simulated using the Theis model.

### C. Drawdown Effects to Protestants' Wells.

Forty-year drawdowns in protestant wells are shown for the cities of Clovis and Portales in Figure 12 and for the other protestants in Figure 13. Forty-year drawdowns in these wells are only reported for Scenario 1. Drawdowns in these wells under Scenarios 2 and 3 are expected to be much larger than those for Scenario 1.

For the City of Portales wells the CPGFM computed drawdowns are reported only since they are located in adjacent model cells to the NMAW pumping wells. Figure 12 shows that simulated drawdowns in these wells were less than 1 foot. The OSE WRSS database reported water column lengths in these wells at the time they were drilled ranging from approximately 60 feet to more than 100 feet (Table 4). The impacts of the proposed NMAW diversions under Scenario 1 should not have significant adverse effects on these city of Portales wells.

Most of the city of Clovis wells are also located in adjacent model cells to NMAW wells except for three wells as shown in Figure 12. The forty-year CPGFM simulated drawdowns in these wells under Scenario 1 ranged from less than a foot in most areas to 1.26 feet in wells CC-00079 and CC-01861. The Theis simulated forty-year drawdown for the three wells (CC-1090, CC-1090-S, and CC-1090-S-2) located in the same model cell as NMAW wells were approximately 5 feet. Table 5 shows water column lengths for only two city of Clovis wells as reported by WRSS. Based on the measurements made when the wells were drilled, the water columns exceeded 70 feet. Drawdown effects due to pumping NMAW wells under Scenario 1 should not have significant adverse impacts on most city of Clovis wells with the exception of the 5 wells mentioned above.

Drawdown effects in all other protestants' wells under Scenario 1 ranged from less than one foot to more than 19 feet as computed by the CPGFM (Figure 13). Forty-year drawdowns computed by the Theis model ranged from less than one (1) foot to

approximately 13.9 feet in wells located in the same model cells as NMAW wells. As shown in Table 6 and based on the WRSS database from measurements following the well drilling, the water column length in these wells ranged from 23 to 121 feet. These wells may not be able to sustain production for forty years.

## V. Water Level Trends

Water level measurements for the Curry County and Portales Basins were queried from the U. S. Geological Survey's Ground Water Site Inventory (GWSI) database. In the area of NMAW pumping wells, representative GWSI wells illustrate water level declines that range from 0.65 to 4.65 feet per year as summarized in Table 7. Hydrographs of water level measurements show water level declines for Figures 14 through Figure 20. In general, the depth to water below ground surface ranges from approximately 100 feet to 300 feet for the portion of the aquifer inclusive of the NMAW pumping wells of Appendix A. Generally, the wells located in the eastern portions of Township 01 North have the greatest water level declines of 3 to 4 feet per year. The Townships 02 North and 01 South have water level declines of 1 foot or more per year. These water level trends indicate that some of the Curry County and Portales Basins will go dry or have insufficient saturated thickness in less than 40 years. As the aquifer is drained, the dry areas will further accelerate water level declines. In the final column of Table 7, the water column estimates highlighted in green are based on 2009 water level measurements subtracted from the reported well depth. As mentioned previously, the water column generally represents the saturated thickness except for the instances noted above in Section IV.B.

## VI. Special Consideration.

The OSE declared the Portales and Curry County Basins in 1950 and 1989, respectively. Located in eastern New Mexico, the basins are hydrologically connected. The primary aquifers in the study area are the High Plains aquifer and more recent sediments representing reworked Ogallala sediments. Water resource administrative guidelines adopted for Portales Valley using a block system approach based on the volume of groundwater stored in each Township expired in 1996, and guidelines have not been adopted for Curry County.

Basin criteria and guidelines have been adopted for a number of basins since the early 1980s based on new groundwater flow models and allowable water level declines. Each of the basin policies is based on the same principles and objectives. The Water Rights Division requested the Hydrology Bureau recommend new computational procedures and basin guidelines for the Curry County and Portales Basins. A model has been completed, and draft guidelines are being developed. The guidelines are very similar to the Lea County basin guidelines that were adopted recently (OSE, 2009). The Lea County basin guidelines limit average drawdown in Critical Management Areas (model cells with less than a 40-year water supply for existing water rights) through 2045 to 0.025 feet per year (1 foot in 40 yrs). Based on a comparison of supply and demand, the Hydrology Bureau recommends that average allowable water level declines on model cells in the Curry County and Portales Basins not exceed 0.025 feet per year. This limit would be imposed on areas with a water supply of less than forty years such as the one under consideration

here. Based on the scenarios evaluated, it is clear that the proposed diversions under this application would have negative effects on the High Plains aquifer by de-watering the area at some of the pumping well locations, and by causing water level declines exceeding 0.025 feet per year in adjacent areas that have less than forty-year supply.

\*8-25-09 Pumping capacities based on Attachment A or additional information provided by NMAW except for CC 296 A and CC 296 S, which were assumed based on the well's water right.

Yellow highlighted wells not part of 9-18-09 NMAW baseline pumping schedule

Green highlighted wells not part of NMAW baseline pumping schedule, yet these wells CC 549 and CC 553 are part of the NMAW future pumping schedule

Blue highlighted well not on Attachment A but appear to be associated with adjacent well file number.

Quarter-quarter section is incorrectly or incompletely entered in NM WRBS database.

\*\*In Attachment A, Well CC 546 is NMAW 32; well CC 547 is NMAW 23; & well P 2921 A is NMAW 71. In 9-18-09 email Well CC 547 is NMAW 32 & Well P 2921 A S is NMAW 71.

Note that for Scenario 2 the Theis model baseline and future pumping used 60 percent of well capacities or full water right allocated for well when no well capacity was available.

Table 2 Drawdowns Simulated by the Theis Model for Scenario 1
